

Strings

Strings

2/67

A *string* is a sequence of characters.
An *alphabet* Σ is the set of possible characters in strings.

Examples of strings:

- C program
- HTML document
- DNA sequence
- Digitised image

Examples of alphabets:

- ASCII
- Unicode
- $\{0,1\}$
- $\{A,C,G,T\}$

... Strings

3/67

Notation:

- $length(P)$... #characters in P
- λ ... *empty* string ($length(\lambda) = 0$)
- Σ^m ... set of all strings of length m over alphabet Σ
- Σ^* ... set of all strings over alphabet Σ

$v\omega$ denotes the *concatenation* of strings v and ω

Note: $length(v\omega) = length(v) + length(\omega)$ $\lambda\omega = \omega = \omega\lambda$

... Strings

4/67

Notation:

- *substring* of P ... any string Q such that $P = vQ\omega$, for some $v, \omega \in \Sigma^*$
- *prefix* of P ... any string Q such that $P = Q\omega$, for some $\omega \in \Sigma^*$
- *suffix* of P ... any string Q such that $P = \omega Q$, for some $\omega \in \Sigma^*$

Exercise #1: Strings

5/67

The string **a/a** of length 3 over the ASCII alphabet has

- how many prefixes?
- how many suffixes?
- how many substrings?

- 4 prefixes: " " "a" "a/" "a/a"
- 4 suffixes: "a/a" "/a" "a" ""
- 6 substrings: " " "a" "/" "a/" "/a" "a/a"

Note:
" " means the same as λ (= empty string)

... Strings

7/67

ASCII (American Standard Code for Information Interchange)

- Specifies mapping of 128 characters to integers 0..127
- The characters encoded include:
 - upper and lower case English letters: A-Z and a-z
 - digits: 0-9
 - common punctuation symbols
 - special non-printing characters: e.g. *newline* and *space*

Ascii	Char	Ascii	Char	Ascii	Char	Ascii	Char
0	Null	32	Space	64	@	96	`
1	Start of heading	33	!	65	A	97	a
2	Start of text	34	"	66	B	98	b
3	End of text	35	#	67	C	99	c
4	End of transmit	36	\$	68	D	100	d
5	Enquiry	37	%	69	E	101	e

30	Record separator	62	>	94	^	126	~
31	Unit separator	63	?	95	_	127	Forward del.

... Strings

8/67

Reminder:

In C a string is an array of `chars` containing ASCII codes

- these arrays have an extra element containing a 0
- the extra 0 can also be written `'\0'` (*null character or null-terminator*)
- convenient because don't have to track the length of the string

Because strings are so common, C provides convenient syntax:

```
char str[] = "hello"; // same as char str[] = {'h','e','l','l','o','\0'};
```

Note: `str[]` will have 6 elements

... Strings

9/67

C provides a number of string manipulation functions via `#include <string.h>`, e.g.

```
strlen() // length of string
strncpy() // copy one string to another
strncat() // concatenate two strings
strstr() // find substring inside string
```

Example:

```
char *strncat(char *dest, char *src, int n)
```

- appends string `src` to the end of `dest` overwriting the `'\0'` at the end of `dest` and adds terminating `'\0'`
- returns start of string `dest`
- will never add more than `n` characters
(If `src` is less than `n` characters long, the remainder of `dest` is filled with `'\0'` characters. Otherwise, `dest` is not null-terminated.)

Pattern Matching

Pattern Matching

11/67

Example (pattern checked *backwards*):

- Text ... abacaab
- Pattern ... abacab

12/67

... Pattern Matching

Given two strings T (*text*) and P (*pattern*), the *pattern matching problem* consists of finding a substring of T equal to P

Applications:

- Text editors
- Search engines
- Biological research

... Pattern Matching

13/67

Naive pattern matching algorithm

- checks for each possible shift of P relative to T
 - until a match is found, or
 - all placements of the pattern have been tried

```
NaiveMatching(T,P):
  Input  text T of length n, pattern P of length m
  Output starting index of a substring of T equal to P
         -1 if no such substring exists

  for all i=0..n-m do
    j=0 // check from left to right
    while j<m ^ T[i+j]=P[j] do // test ith shift of pattern
      j=j+1
      if j=m then
        return i // entire pattern checked
      end if
    end while
  end for
  return -1 // no match found
```

Analysis of Naive Pattern Matching

14/67

Naive pattern matching runs in $O(n \cdot m)$

Examples of worst case (forward checking):

- $T = \text{aaa...ah}$
- $P = \text{aaah}$
- may occur in DNA sequences
- unlikely in English text

Exercise #2: Naive Matching

15/67

Suppose all characters in P are different.

Can you accelerate `NaiveMatching` to run in $O(n)$ on an n -character text T ?

When a mismatch occurs between $P[j]$ and $T[i+j]$, shift the pattern all the way to align $P[0]$ with $T[i+j]$

⇒ each character in T checked at most twice

Example:

abcda**bc**deabcc abcdab**cd**deabcc
 abcde**xxxxxxx** xxx**abc**de

Boyer-Moore Algorithm

17/67

The *Boyer-Moore* pattern matching algorithm is based on two heuristics:

- *Looking-glass heuristic*: Compare P with subsequence of T moving *backwards*
- *Character-jump heuristic*: When a mismatch occurs at $T[i]=c$
 - if P contains c ⇒ shift P so as to align the **last** occurrence of c in P with $T[i]$
 - otherwise ⇒ shift P so as to align $P[0]$ with $T[i+1]$ (a.k.a. "big jump")

... Boyer-Moore Algorithm

18/67

Example:

... Boyer-Moore Algorithm

19/67

Boyer-Moore algorithm preprocesses pattern P and alphabet Σ to build

- *last-occurrence function* L
 - L maps Σ to integers such that $L(c)$ is defined as
 - the largest index i such that $P[i]=c$, or
 - -1 if no such index exists

Example: $\Sigma = \{a, b, c, d\}$, $P = acab$

c	a	b	c	d
$L(c)$	2	3	1	-1

- L can be represented by an array indexed by the numeric codes of the characters
- L can be computed in $O(m+s)$ time (m ... length of pattern, s ... size of Σ)

... Boyer-Moore Algorithm

BoyerMooreMatch(T, P, Σ):

Input text T of length n , pattern P of length m , alphabet Σ
Output starting index of a substring of T equal to P
 -1 if no such substring exists

```

L=lastOccurrenceFunction(P,Σ)
i=m-1, j=m-1                                // start at end of pattern
repeat
  if T[i]=P[j] then
    if j=0 then
      return i                                // match found at i
    else
      i=i-1, j=j-1
    end if
  else
    i=i+m-min(j, 1+L[T[i]])                  // character-jump
    j=m-1
  end if
until i≥n
return -1                                     // no match

```

- Biggest jump (m characters ahead) occurs when $L[T[i]] = -1$

... Boyer-Moore Algorithm

21/67

Case 1: $j \leq 1+L[c]$

Case 2: $1+L[c] < j$

Exercise #3: Boyer-Moore algorithm

22/67

For the alphabet $\Sigma = \{a, b, c, d\}$

1. compute last-occurrence function L for pattern $P = \text{abacab}$
2. trace Boyer-More on P and text $T = \text{abacaabadcabacabaabb}$
 - how many comparisons are needed?

c	a	b	c	d
$L(c)$	4	5	3	-1

13 comparisons in total

... Boyer-More Algorithm

24/67

Analysis of Boyer-More algorithm:

- Runs in $O(nm+s)$ time
 - m ... length of pattern n ... length of text s ... size of alphabet
- Example of worst case:
 - $T = \text{aaa} \dots \text{a}$
 - $P = \text{baaa}$
- Worst case may occur in images and DNA sequences but unlikely in English texts
 - ⇒ Boyer-More significantly faster than naive matching on English text

Knuth-Morris-Pratt Algorithm

25/67

The *Knuth-Morris-Pratt* algorithm ...

- compares the pattern to the text *left-to-right*
- but shifts the pattern more intelligently than the naive algorithm

Reminder:

- Q is a *prefix* of P ... $P = Q\omega$, for some $\omega \in \Sigma^*$
- Q is a *suffix* of P ... $P = \omega Q$, for some $\omega \in \Sigma^*$

... Knuth-Morris-Pratt Algorithm

26/67

When a mismatch occurs ...

- what is the most we can shift the pattern to avoid redundant comparisons?
- Answer: the largest *prefix* of $P[0..j]$ that is a *suffix* of $P[1..j]$

... Knuth-Morris-Pratt Algorithm

27/67

KMP preprocesses the pattern to find matches of its prefixes with itself

- *Failure function* $F(j)$ defined as
 - the size of the *largest prefix* of $P[0..j]$ that is also a *suffix* of $P[1..j]$
- if mismatch occurs at $P_j \Rightarrow$ advance j to $F(j-1)$

Example: $P = \text{abaaba}$

j	0	1	2	3	4	5
P_j	a	b	a	a	b	a
$F(j)$	0	0	1	1	2	3

... Knuth-Morris-Pratt Algorithm

28/67

KMPMatch(T, P) :

Input text T of length n , pattern P of length m
Output starting index of a substring of T equal to P
 -1 if no such substring exists

```

F=failureFunction(P)
i=0, j=0                // start from left
while i<n do
  if T[i]=P[j] then
    if j=m-1 then
      return i-j        // match found at i-j
    else
      i=i+1, j=j+1
    end if
  else
    // mismatch at P[j]
    if j>0 then
      j=F[j-1]          // resume comparing P at F[j-1]
    else
      i=i+1
    end if
  end if
end while
return -1                // no match
  
```

Exercise #4: KMP-Algorithm

29/67

- compute failure function F for pattern $P = \text{abacab}$
- trace Knuth-Morris-Pratt on P and text $T = \text{abacaabaccabacabaabb}$
 - how many comparisons are needed?

j	0	1	2	3	4	5
P_j	a	b	a	c	a	b
$F(j)$	0	0	1	0	1	2

19 comparisons in total

... Knuth-Morris-Pratt Algorithm

31/67

Construction of the failure function is similar to the KMP algorithm itself:

```

failureFunction(P):
  Input pattern P of length m
  Output failure function for P

  F[0]=0
  i=1, j=0
  while i<m do
    if P[i]=P[j] then    // we have matched j+1 characters
      F[i]=j+1
      i=i+1, j=j+1
    else if j>0 then    // use failure function to shift P
      j=F[j-1]
    else
      F[i]=0            // no match
      i=i+1
    end if
  end while
  return F
  
```

... Knuth-Morris-Pratt Algorithm

32/67

Analysis of failure function computation:

- At each iteration of the while-loop, either
 - i increases by one, or
 - the "shift amount" $i-j$ increases by at least one (observe that $F(j-1) < j$)
- Hence, there are no more than $2 \cdot m$ iterations of the while-loop

⇒ failure function can be computed in $O(m)$ time

... Knuth-Morris-Pratt Algorithm

33/67

Analysis of Knuth-Morris-Pratt algorithm:

- Failure function can be computed in $O(m)$ time
- At each iteration of the while-loop, either
 - i increases by one, or
 - the "shift amount" $i-j$ increases by at least one (observe that $F(j-1) < j$)
- Hence, there are no more than $2 \cdot n$ iterations of the while-loop

⇒ KMP's algorithm runs in *optimal time* $O(m+n)$

Boyer-Moore vs KMP

34/67

Boyer-Moore algorithm

- decides how far to jump ahead based on the mismatched character in the text
- works best on large alphabets and natural language texts (e.g. English)

Knuth-Morris-Pratt algorithm

- uses information embodied in the pattern to determine where the next match could begin
- works best on small alphabets (e.g. A,C,G,T)

For the keen: The article "[Average running time of the Boyer-Moore-Horspool algorithm](#)" shows that the time is inversely proportional to size of alphabet

Word Matching With Tries

Preprocessing Strings

36/67

Preprocessing the *pattern* speeds up pattern matching queries

- After preprocessing *P*, KMP algorithm performs pattern matching in time proportional to the text length

If the text is large, immutable and searched for often (e.g., works by Shakespeare)

- we can preprocess the *text* instead of the pattern

... Preprocessing Strings

37/67

A *trie* ...

- is a compact data structure for representing a set of strings
 - e.g. all the words in a text, a dictionary etc.
- supports pattern matching queries in time proportional to the pattern size

Note: Trie comes from *retrieval*, but is pronounced like "try" to distinguish it from "tree"

Tries

38/67

Reminder (COMP9021):

Tries are trees organised using parts of keys (rather than whole keys)

... Tries

39/67

Each node in a trie ...

- contains one part of a key (typically one character)
- may have up to 26 children
- may be tagged as a "finishing" node
- but even "finishing" nodes may have children

Depth *d* of trie = length of longest key value

Cost of searching $O(d)$ (independent of *n*)

... Tries

40/67

Possible trie representation:

```
#define ALPHABET_SIZE 26

typedef struct Node *Trie;

typedef struct Node {
    bool finish;      // last char in key?
    Item data;        // no Item if !finish
    Trie child[ALPHABET_SIZE];
} Node;

typedef char *Key;
```

... Tries

41/67

Note: Can also use BST-like nodes for more space-efficient implementation of tries

Trie Operations

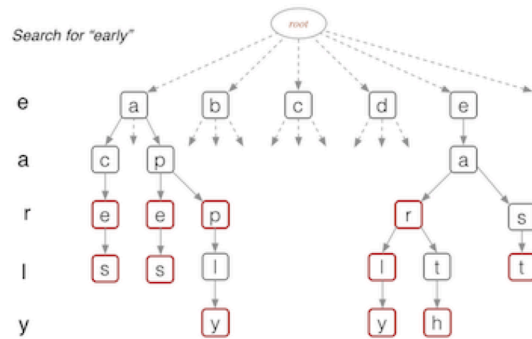

42/67

Basic operations on tries:

1. search for a key
2. insert a key

Trie Operations

43/67

... Trie Operations

44/67

Traversing a path, using char-by-char from Key:

```
find(trie, key):
    Input  trie, key
    Output pointer to element in trie if key found
           NULL otherwise

    node=trie
    for each char in key do
        if node.child[char] exists then
```

```
        node=node.child[char] // move down one level
    else
        return NULL
    end if
end for
if node.finish then // "finishing" node reached?
    return node
else
    return NULL
end if
```

... Trie Operations

45/67

Insertion into Trie:

```
insert(trie, item, key):
    Input  trie, item with key of length m
    Output trie with item inserted

    if trie is empty then
        t=new trie node
    end if
    if m=0 then
        t.finish=true, t.data=item
    else
        t.child[key[0]]=insert(t.child[key[0]], item, key[1..m-1])
    end if
    return t
```

... Trie Operations

46/67

Analysis of standard tries:

- $O(n)$ space
- insertion and search in time $O(d \cdot m)$
 - n ... total size of text (e.g. sum of lengths of all strings in a given dictionary)
 - m ... size of the string parameter of the operation (the "key")
 - d ... size of the underlying alphabet (e.g. 26)

Word Matching With Tries

Word Matching with Tries

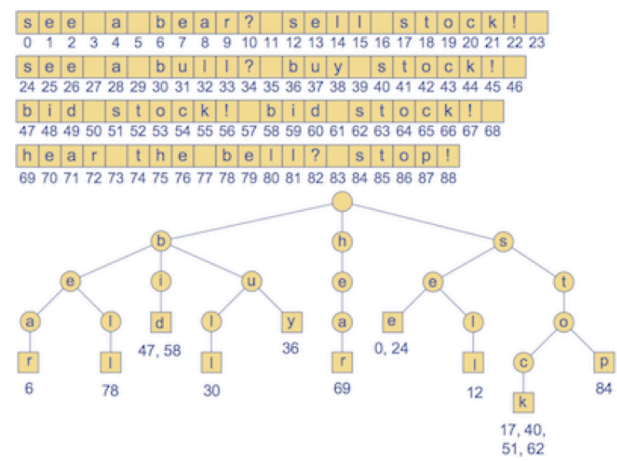

48/67

Preprocessing the text:

1. Insert all searchable words of a text into a trie
2. Each leaf stores the occurrence(s) of the associated word in the text

... Word Matching with Tries

Example text and corresponding trie of searchable words:

- nodes store *ranges of indices* instead of substrings
 - use triple (i,j,k) to represent substring $S[i][j..k]$
- requires $O(s)$ space ($s = \text{\#strings in array } S$)

Example:

Compressed Tries

Compressed tries ...

- have internal nodes of degree ≥ 2
- are obtained from standard tries by compressing "redundant" chains of nodes

Example:

Pattern Matching With Suffix Tries

The *suffix trie* of a text T is the compressed trie of all the suffixes of T

Example:

... Pattern Matching With Suffix Tries

Compact representation:

... Compressed Tries

Possible compact representation of a compressed trie to encode an array S of strings:

Input:

- compact suffix trie for text T
- pattern P

Goal:

- find starting index of a substring of T equal to P

... Pattern Matching With Suffix Tries

55/67

```

suffixTrieMatch(trie,P):
  Input compact suffix trie for text T, pattern P of length m
  Output starting index of a substring of T equal to P
          -1 if no such substring exists

  j=0, v=root of trie
  repeat
    // we have matched j+1 characters
    if ∃wchildren(v) such that P[j]=T[start(w)] then
      i=start(w)           // start(w) is the start index of w
      x=end(w)-i+1         // end(w) is the end index of w
      if m≤x then // length of suffix ≤ length of the node label?
        if P[j..j+m-1]=T[i..i+m-1] then
          return i-j       // match at i-j
        else
          return -1        // no match
      else if P[j..j+x-1]=T[i..i+x-1] then
        j=j+x, m=m-x       // update suffix start index and length
        v=w                // move down one level
      else return -1       // no match
    end if
  else
    return -1
  end if
until v is leaf node
return -1                  // no match

```

... Pattern Matching With Suffix Tries

56/67

Analysis of pattern matching using suffix tries:

Suffix trie for a text of size n ...

- can be constructed in $O(n)$ time
- uses $O(n)$ space
- supports pattern matching queries in $O(s \cdot m)$ time
 - m ... length of the pattern
 - s ... size of the alphabet

Text Compression

Text Compression

58/67

Problem: Efficiently encode a given string X by a smaller string Y

Applications:

- Save memory and/or bandwidth

Huffman's algorithm

- computes frequency $f(c)$ for each character c
- encodes high-frequency characters with short code
- no code word is a prefix of another code word
- uses optimal *encoding tree* to determine the code words

... Text Compression

59/67

Code ... mapping of each character to a binary code word

Prefix code ... binary code such that no code word is prefix of another code word

Encoding tree ...

- represents a prefix code
- each leaf stores a character
- code word given by the path from the root to the leaf (0 for left child, 1 for right child)

... Text Compression

60/67

Example:

... Text Compression

61/67

Text compression problem

Given a text T , find a prefix code that yields the shortest encoding of T

- short codewords for frequent characters
- long code words for rare characters

... Text Compression

62/67

Example: $T = \text{abracadabra}$

T_1 requires 29 bits to encode text T ,
 T_2 requires 24 bits

... Text Compression

63/67

Huffman's algorithm

- computes frequency $f(c)$ for each character
- successively combines pairs of lowest-frequency characters to build encoding tree "bottom-up"

Example: abracadabra

Huffman Code

64/67

Huffman's algorithm using **priority queue**:

HuffmanCode(T):

Input string T of size n

Output optimal encoding tree for T

compute frequency array

$Q = \text{new priority queue}$

for all characters c **do**

$T = \text{new single-node tree storing } c$

$\text{join}(Q, T)$ with $\text{frequency}(c)$ as key

end for

while $|Q| \geq 2$ **do**

$f_1 = Q.\text{minKey}()$, $T_1 = \text{leave}(Q)$

$f_2 = Q.\text{minKey}()$, $T_2 = \text{leave}(Q)$

$T = \text{new tree node with subtrees } T_1 \text{ and } T_2$

$\text{join}(Q, T)$ with $f_1 + f_2$ as key

end while

| **return** $\text{leave}(Q)$

... Huffman Code

65/67

Larger example: a fast runner need never be afraid of the dark

... Huffman Code

66/67

Analysis of Huffman's algorithm:

- $O(n + d \log d)$ time
 - n ... length of the input text T
 - d ... number of distinct characters in T

Summary

67/67

- Alphabets and words
- Pattern matching
 - Boyer-Moore, Knuth-Morris-Pratt
- Tries
- Text compression
 - Huffman code
- Suggested reading:
 - Tries ... Sedgewick, Ch.15.2
